ABSTRACT

This newsletter issue describes 3-wheeled scooters and van lifts that can assist a person with a disability to drive independently or have access to transportation. The section on van lifts compares hydraulic lifts and electric lifts, lists manufacturers, and offers an "assessment quiz" outlining factors to consider in selecting a van lift. In the section on battery-powered scooters and 3-wheelers, such features are described as power and drive systems, batteries, steering and control features, braking, seating, and armrests. A list of manufacturers and questions to consider when selecting a 3-wheeled scooter are included. (JDD)

### Editor's note:

A "secret strength" here at the PAM Centre is the establishment of relationships and communication links both near and far, through our newsletter exchange. Our network with those of kindred interests involves the regular interchange of publications with some 56 organizations.

John Stevens, with the Center for Rehabilitation Technology Services of the South Carolina Vocational Rehabilitation Department, edits their Information Support Packets. We especially liked the Assessment Quiz, Considerations in Selecting a Van Lift, and have permission to further share the following narrative and quiz with our readers.

For specific information concerning dealers specializing in adapted vans and driving equipment, as well as descriptions of specific products, call the PAM Assistance Centre toll free between the hours of 9:00 and 5:00 weekdays, or simply write to us.

### Van lifts:

In many cases, the only practical method for a person with a disability to independently drive or have access to transportation is through the use of a van equipped with an automatic lift. There are several different brands and designs available with a variety of options. Depending on the make and model of van to be equipped, a lift can be installed in the side or rear door. A "fully automatic" lift can be equipped in such a way so that many wheelchair users can independently enter and exit the van. A "semi-automatic" lift is more commonly used in paratransit applications, or when an attendant or other family member will be driving the vehicle. Van lifts can be either "electro-hydraulics" or "all electric" in terms of operational design. Each design has certain advantages and disadvantages. These are briefly described below.

### Hydraulic lifts:

These lifts are more commonly used in commercial applications. Paratransit companies, health care institutions, rehabilitation centers, and school districts tend to use lifts that are of the hydraulic design. These lifts have fewer switches to operate so employees can be quickly trained in their operation. They are serviceable by more dealers and replacement parts are, in some cases, available locally. Most hydraulic lifts are heavy and durable. They are often capable of lifting more weight than electric lifts. Their manual back-up systems are easy to understand and use.

## *Electric lifts:*

The "all electric" lifts have different advantages. Because they do not require hydraulic fluid, they are very popular in the colder areas of the country, and with disabled consumers who have their own, custom vehicles. Most electric lifts are lighter in weight, usually not more than 180 pounds. There are no hydraulic hoses or fittings to leak and soil the van floor. The "all electric" principle allows the lift to operate consistently in a variety of climates and temperatures. They are available in the "platform" or "swingout" design. These lifts require a very low operating amperage and usually operate quite well using the vehicle's standard 12-volt DC factory battery. Some brands are quieter when operating. The electric lifts, due to the lighter weight, are more popular for use with the newer mini vans.

## *Manufacturers of Van Lifts \**

Assessment quiz \*

# Considerations in selecting a van lift:

1. Will the lift handle a minimum of 500 pounds?  
 YES       NO
2. Will I need a "dual entry" platform to aid in tight parking situations?  
 YES       NO
3. Is there a dealer within reasonable distance who can provide service?  
 YES       NO
4. Can this lift be removed, transferred, and reinstalled in another van if the need arises?  
 YES       NO
5. Does this lift have a manual back-up system that can be easily operated by a friend or family member?  
 YES       NO
6. If I live near a coastal area where the air is damp and salty, will this lift rust easily?  
 YES       NO
7. Has this lift been tested for safety and dependability by the appropriate agencies?  
 YES       NO
8. Does this carry at least a 1 year warranty that includes parts and labor?  
 YES       NO
9. Are there dealers in other states that can provide service if I should need it while traveling?  
 YES       NO
10. Do I need a lift that will allow non-disabled passengers to also enter the van when the lift is in the folded position?  
 YES       NO

# Battery-Powered Scooters and 3-Wheelers

## *Power and Drive Systems*

Most 3-wheelers have either a front or rear wheel drive design. Each has its advantages and disadvantages. Those with a single, front wheel drive are better suited for indoor use on firm, level surfaces. The majority are powered by two 12-volt batteries although a few have a single 12-volt battery as their power source. Those using a single 12-volt system will be limited in range and grade-climbing ability, but due to their frame will allow a shorter turning radius and thus better maneuverability within the home. In addition, front wheel drive models tend to weigh less, thus making them easier to disassemble and load into an automobile or push manually in the event of a power failure.

Rapidly gaining popularity are models with a dual rear wheel drive system. This design provides better traction due to the twin action of the rear wheels and the increased weight directly over the rear axle. The rear wheel drive models are larger in size and typically use a 24-volt dual battery system. This delivers a longer range per charge than a single battery system. These models are generally better suited to use outdoors because they are more stable and provide better traction in grass or sand. Also, the rear wheel drive models can climb moderate inclines with a greater speed than front wheel drive vehicles. A disadvantage is that these models are heavier and require more time and effort to disassemble and load into a car. Quite often a trunk lift, lift-equipped van, or other powered lift will be needed to transport the rear wheel drive models. In addition, rear wheel drive scooters may not be as practical for indoor use and often have to be used in conjunction with a standard manual wheelchair or else a smaller 3-wheeler indoors.

## *Batteries*

Most of the 3-wheelers available today use "gel" or "lead acid" deep cycle batteries. Lead acid batteries are somewhat less expensive and can have a longer life, but require periodic maintenance. Gel batteries are more costly, but require no maintenance outside of regular charging. One major advantage of gel batteries is that commercial airlines will allow them aboard their aircraft if air travel with the scooter is necessary.

## *Steering and Control Features*

The most popular and widely used steering method for 3-wheelers is the front handlebar design. It is similar to a bicycle handlebar except that it is shorter in horizontal width. Direction and ground speed are controlled by a lever on the handlebar which can be adjusted to a variety of positions to accommodate individual needs and capabilities. Usually, the motor is activated by a push, pull, or squeeze of the finger, thumb, hand, or wrist. In conjunction with a variable speed lever, several manufacturers use a Hi/Lo speed switch or an adjustable "maximum speed" setting. These

features allow the user to individually tailor the ground speed and sensitivity of the controls. Most models of 3-wheeler also have an adjustment to tilt the handlebar from 90 degrees to 30 degrees. This enables the user to position the controls for the ultimate in convenience. The average top speed for most 3-wheelers is around 5.5 miles per hour, although this may vary depending on the particular make and model and the terrain over which it is being driven.

## ***Braking***

Braking systems used on 3-wheeler are usually one of four types: manual, electromechanical, regenerative, and dynamic. Regenerative and dynamic generally work together, and the scooter will stop when the user takes his hand off the speed control. Electromechanical braking systems, introduced in the past two to three years, enable a scooter to stop on a hill. Without electromechanical braking, 3-wheeler may not be as safe to operate in hilly terrain. A manual braking system is usually a simple hand lever that is used to engage an immobilization device against one or more wheels. This is considered by many users to be more of a "stabilization" device rather than braking.

## ***Seating and Armrests***

The disability of the user will normally determine what seat options are needed. Most manufacturers offer at least two options in upholstery and cushioning. A disabled individual who lacks normal sensation in the thighs and buttocks will often need a thicker cushion or often a "prescription" cushion. On the other hand, if the person is sensate and can tolerate longer sitting times, they may need nothing more than a plastic molded or vinyl covered seat. Finally, if the user will need the 3-wheeler to assist in activities of daily living such as doing laundry or standing at a sink, a powered elevating seat with a swivel feature might be necessary. Considerable thought should be given as to what activities will be done from the device prior to ordering seating features. Also, some thought should be given to armrests and whether they are necessary. Most users find they aid in trunk balance and in weight shifts. Most manufacturers offer armrests that flip up and detach to aid in transfers.

*The Assessment Quiz on the following page should be used as a checklist when purchasing a 3-wheeled scooter. Answer these questions as they pertain to your needs or those of the person using the device.*

**Assessment Quiz \***

# Questions to consider when shopping for a 3-wheeled scooter:

---

-  1. Will this device be used primarily indoors or outdoors? What percentage of time for each?  
 YES    NO
  
2. Can the user independently disassemble and load the scooter into a car, if needed?  
 YES    NO
  
3. Can the user independently attend to minor maintenance such as the batteries, brake adjustment, tire air pressure and similar items?  
 YES    NO
  
4. Will this 3-wheeler operate on both "gel" or "lead acid" batteries? Is there a nearby source to buy batteries at a reasonable cost?  
 YES    NO
  
5. Will the dealer provide service for the vehicle, or will the user have to deal with a manufacturer by phone or correspondence?  
 YES    NO
  
6. When disassembled, will the 3-wheeler fit into the car's trunk, luggage area, or back seat?  
 YES    NO
  
7. Does the dealer also offer a lifting mechanism compatible with the scooter to aid with loading and unloading? Will the dealer install, adjust, and service the lift?  
 YES    NO
  
8. Is the user's home architecturally accessible to the extent that using a 3-wheeler indoors will be practical? Does the home have a ramp? How wide are the doorways?  
 YES    NO
  
9. How long is the manufacturer's warranty? Does it include parts and labor?  
 YES    NO
  
10. Does the dealer stock replacement parts or will they have to be ordered? How long will this take?  
 YES    NO
  
11. How far away does the user live from the nearest factory-authorized dealer?  
 YES    NO
  
12. Will the user need special features such as a front basket, swivel seat, or powered elevating seat? Are the added conveniences worth the additional costs?  
 YES    NO
  
13. Does the 3-wheeler under consideration offer enough adjustments and add-on features to accommodate the user's disability five years in the future?  
 YES    NO

## SCOOTERS

**The popularity of small, transportable 3-wheeled scooters and similar mobility devices has increased dramatically in recent years. These products enable persons with disabilities to remain active in their homes, communities, and places of employment.**

While 3-wheelers can assist individuals with all types of disabilities, they are primarily designed to aid the "mobility limited" person. Usually, this is a person who has limited ability to ambulate for distances that would be considered normal for a nondisabled person. Individuals with disabilities such as multiple sclerosis, heart and lung conditions, arthritis, or other conditions that limit one's endurance and stamina are good candidates for 3-wheeled vehicles.

Three-wheelers are available in a variety of designs and sizes. Various options and accessories are offered to help meet a person's individual needs. Anyone who is considering the purchase of a 3-wheeler should first shop around, compare prices, and evaluate their own needs before making a decision. This guide can assist them in their efforts.
